Post-tuberculosis infection (PTBI) refers to the reactivation of latent Mycobacterium tuberculosis infection. This study was conducted to determine the efficacy of the standard four-drug regimen for PTBI (isoniazid [INH], rifampicin [RFP], pyrazinamide [PZA], and ethambutol [EMB]) in a high-risk population. We retrospectively reviewed the medical records of 459 patients who received the standard 4-drug regimen. Fourteen (3.0%) patients developed PTBI within 1 year of cessation of therapy, and another 23 (5.1%) patients developed the condition between 1 and 4 years later. There was no significant difference in the incidence of PTBI between the first and second year. The cumulative incidences of PTBI 1, 2, and 3 years after the completion of therapy were 9.0% (95% confidence interval [CI]: 5.8-12.3), 15.5% (95% CI: 11.0-20.0), and 18.5% (95% CI: 13.3-23.8), respectively. The cumulative incidence of PTBI within 4 years of completion of therapy was 10.1% (95% CI: 6.2-14.0). Furthermore, the high-risk patients with a body mass index (BMI) ≥ 23 kg/m² had a significantly increased risk of PTBI when compared with the normal BMI group. The four-drug regimen may not be effective for the prevention of PTBI in a high-risk population. Thus, treatment for PTBI needs to be redefined. Chromosome damage by oxidized and alkylated nucleotides. Reactive oxygen species (ROS) cause a variety of biological effects by reacting with cell components. In the present work, we have studied the effects of oxidized and alkylated nucleotides on chromosome structure, specifically chromosome aberrations, in human lymphocytes. As the presence of DNA- and RNA-containing structures on the nuclear surface induces spontaneous DNA damage in vitro, we first investigated the effect of oxidized and alkylated nucleotides on the distribution of these structures. After drug treatment, we found a significant decrease of both the number of chromosome ab
